

CMP User Group Winter 2024

# Spectroscopic Analysis and Machine Learning to Expedite Oxide Planarization Development (SAMPLE-OPD)

**Shanmukh Kutagulla**, Richard F Vreeland, Glenn Whitener, Ken Delbridge, Thomas Hoff, Eric Jorgenson, Jeff Armstrong, William Brezinski, Herbert Barnett, Eric Mattson, Shouvik Banerjee, Rupak Thapa, Christopher Pell, Cindy Taylor, Nam Nguyen, Camille McGill, Abraham Trejo

Intel Technology Research

# Agenda

- 01 The Problem: CMP is Inherently Multivariate
- 02 Simplifying the System: Experimental Design
- 03 Significance and Correlation of Species to Polish Rates
- 04 Predicting Polish Rate with a Machine Learning Model
- 05 Future Work & Advancement

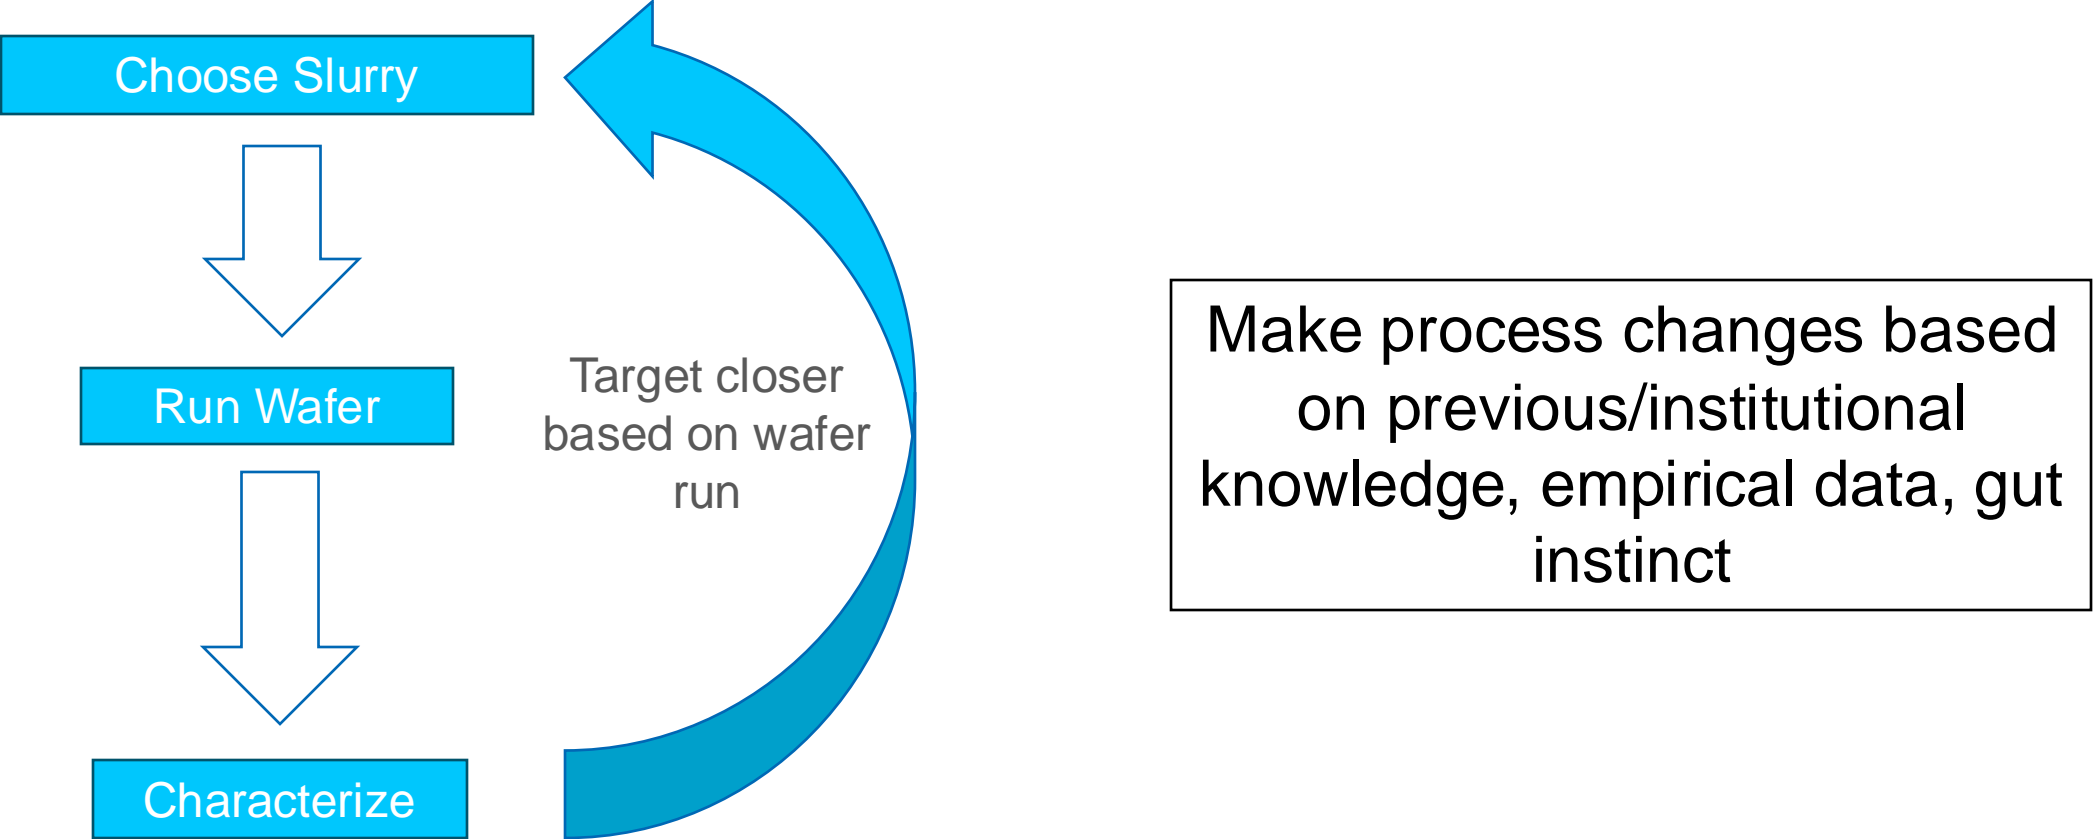

# The CMP Process & Current Challenges

Many parameters that all interact, making 1:1 modeling difficult. Development is primarily empirical.

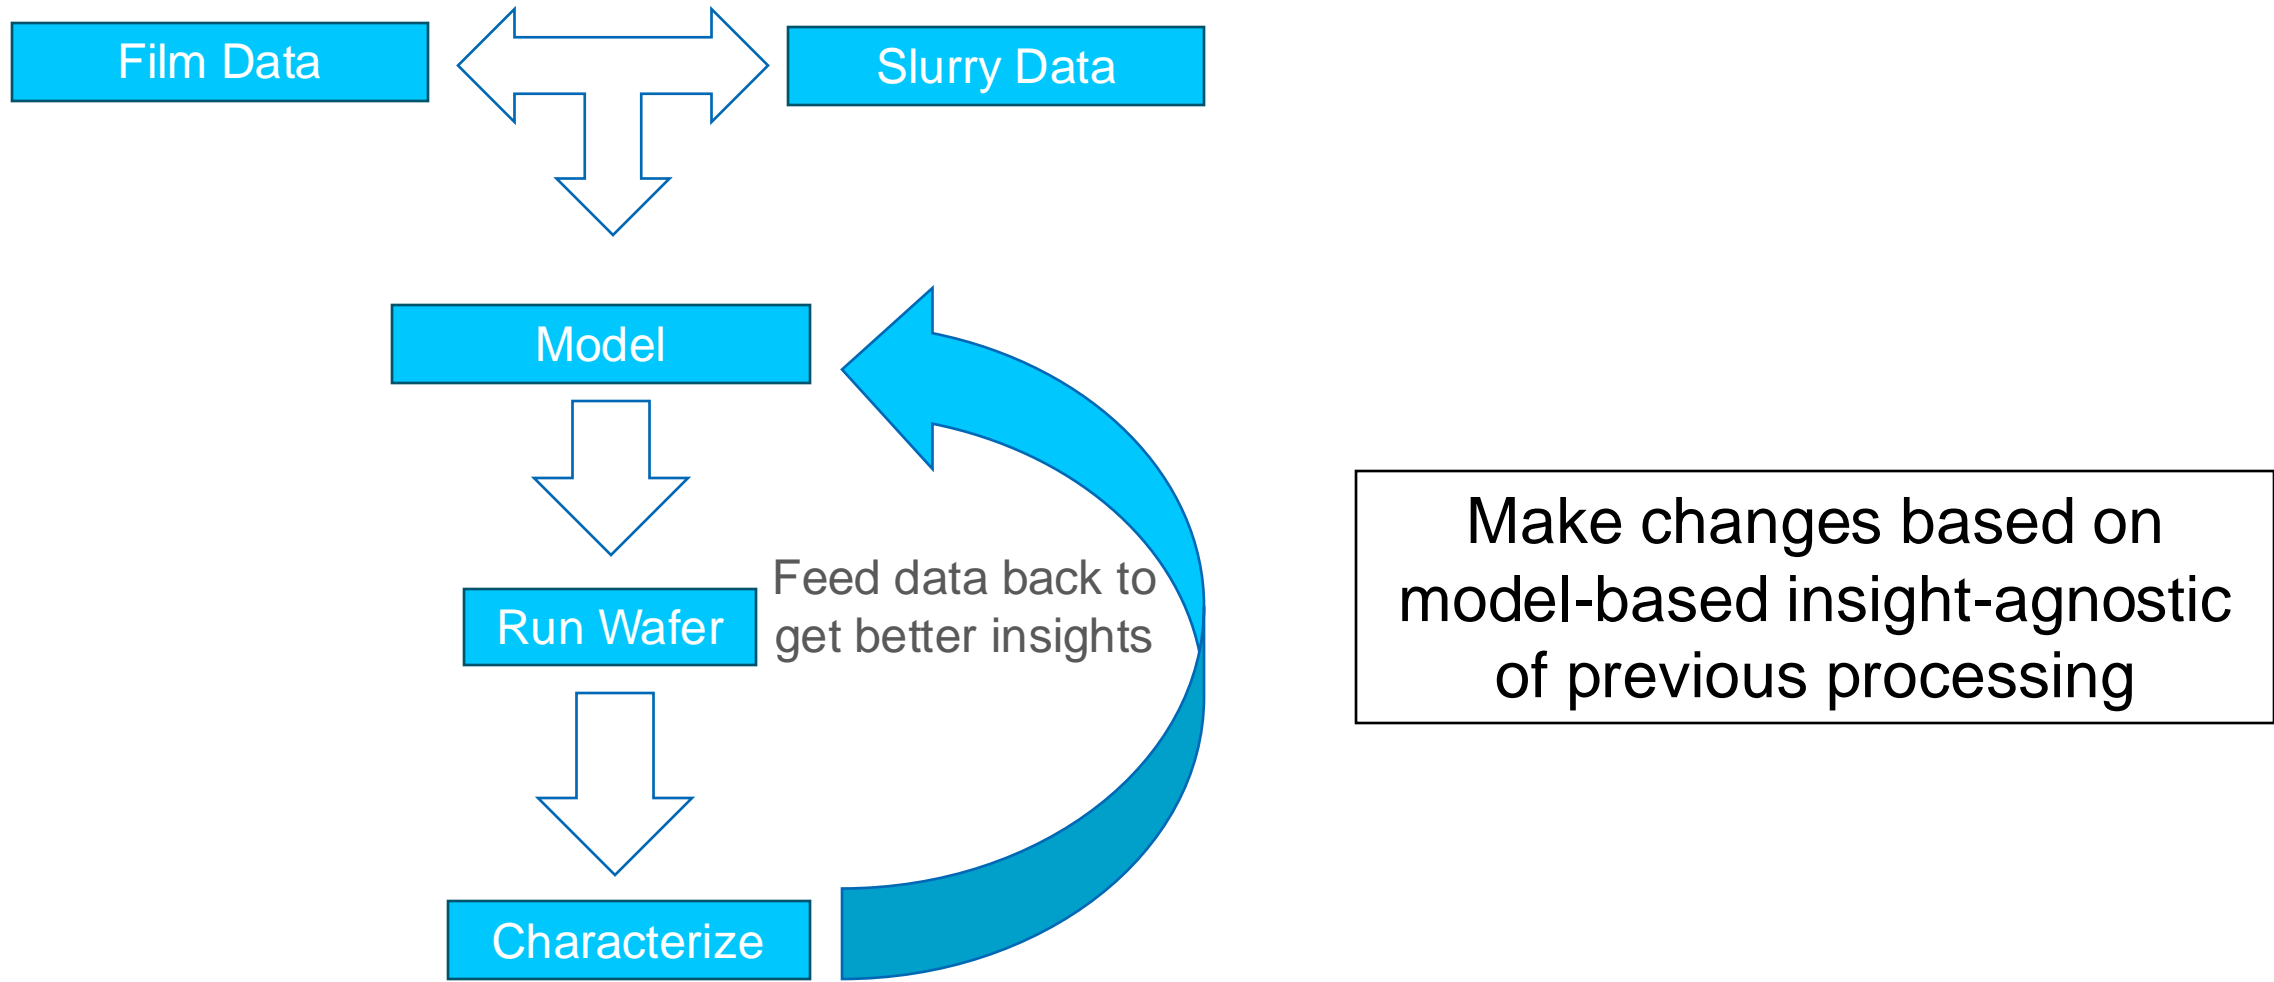

Seo, J. A review on chemical and mechanical phenomena at the wafer interface during chemical mechanical planarization. *Journal of Materials Research* **36**, 235–257 (2021). <https://doi.org/10.1557/s43578-020-00060-x>

# Current CMP Development- High Throughput Experimentation

\*sometimes, you get it right the first time using onboard metrology

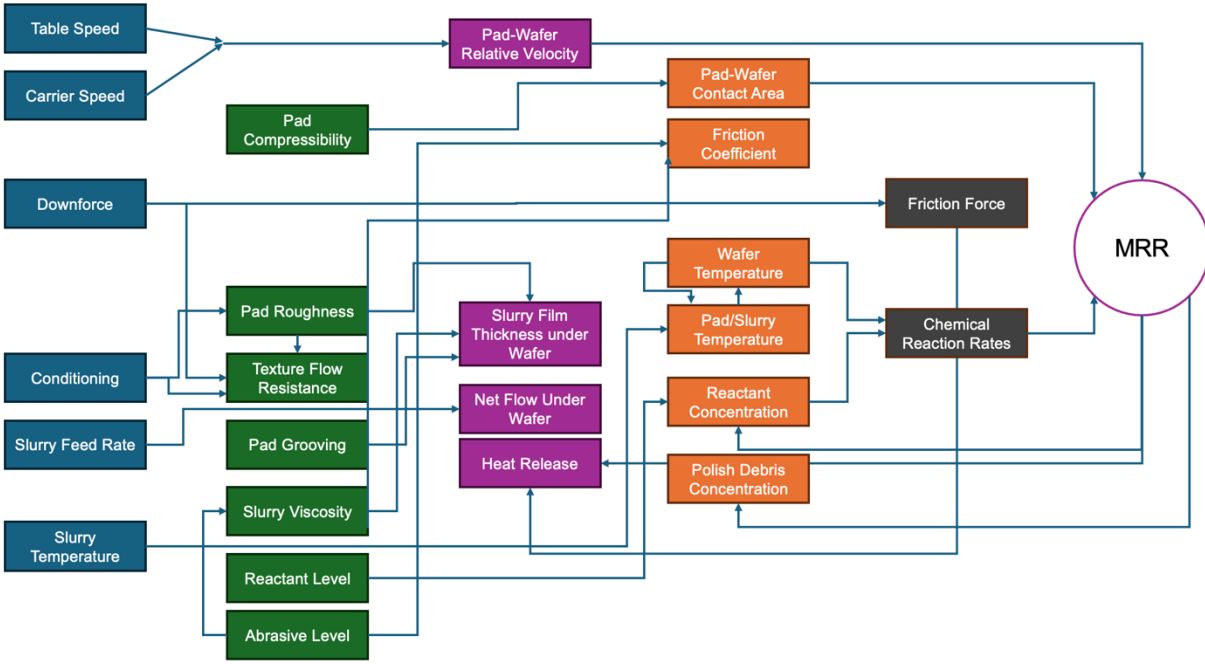

# The Vision for CMP Development

Do not need to start from zero when working on new films

# Can we develop such a model with AI?

- It has never been easier to study interrelated variables using AI techniques
- Previous attempts at modeling utilized 20 or more descriptors and thousands of data points to predict polish rates- infeasible for R&D
- Select features of importance based on surface interactions and basic spectroscopy data

# Can we develop a model in the low data regime?

# Can We Use Noncontact Metrology to Predict Polish Rates?

Custom Blends  
from Fujimi

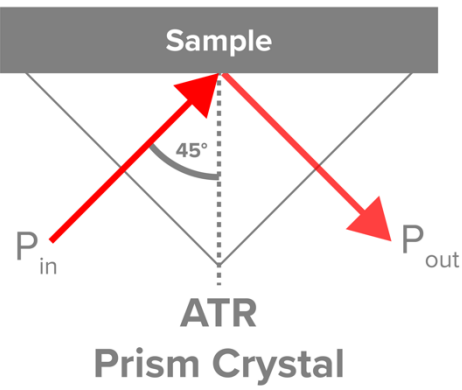

Slurry	Particle Size	Material
X	30	SiO <sub>2</sub>
Y	30	“Low Silanol” SiO <sub>2</sub>
2X	75	SiO <sub>2</sub>

16 unique films

Films	Deposition Information	Steam Treatment Conditions
fCVD 1	fCVD- Thermal Cure	No Process - NP
fCVD 2	fCVD- UV Cure	200 C (1 hr) + 500 C (1 hr)- 200/500
PECVD	PECVD (SiH <sub>4</sub> +N <sub>2</sub> O)	500 C (2 hr) - 500
HDP	High Density Plasma (SiH <sub>4</sub> +O <sub>2</sub> )	700 C (2 hr) - 700

3 slurries x 4 films x 4 steam treatments= **48**  
**polish rates**

# Our Toolkit

ATR-FTIR

MIR-FTIR

ToF-SIMS

Water Contact Angles (WCA)

X-ray Photoelectron Spectroscopy (XPS)

Density Measurements

Characterization battery was completed on all wafers post growth, and on selected “interesting” coupons

# Experimental Design

Based on the collected data, we can identify some immediate trends on factors that affect polish rates

# Steam Annealing Decreases Polish Rates – With Notable Exceptions

**Particle X**

**Particle Y (Surface Engineered)**

**Particle 2X**

No Process films for fCVD 1, fCVD 2, & PECVD show reduced polish rates with Particle Y while the rest show enhanced rates

# The Role of Different Chemical Species in Films

# All 3 Particle Y Nonpolishing Films Show >1 at% N

A small amount of nitrogen causes large scale effects!

# Why Does 1-3% Nitrogen Reduce Polish Rate With Particle Y?

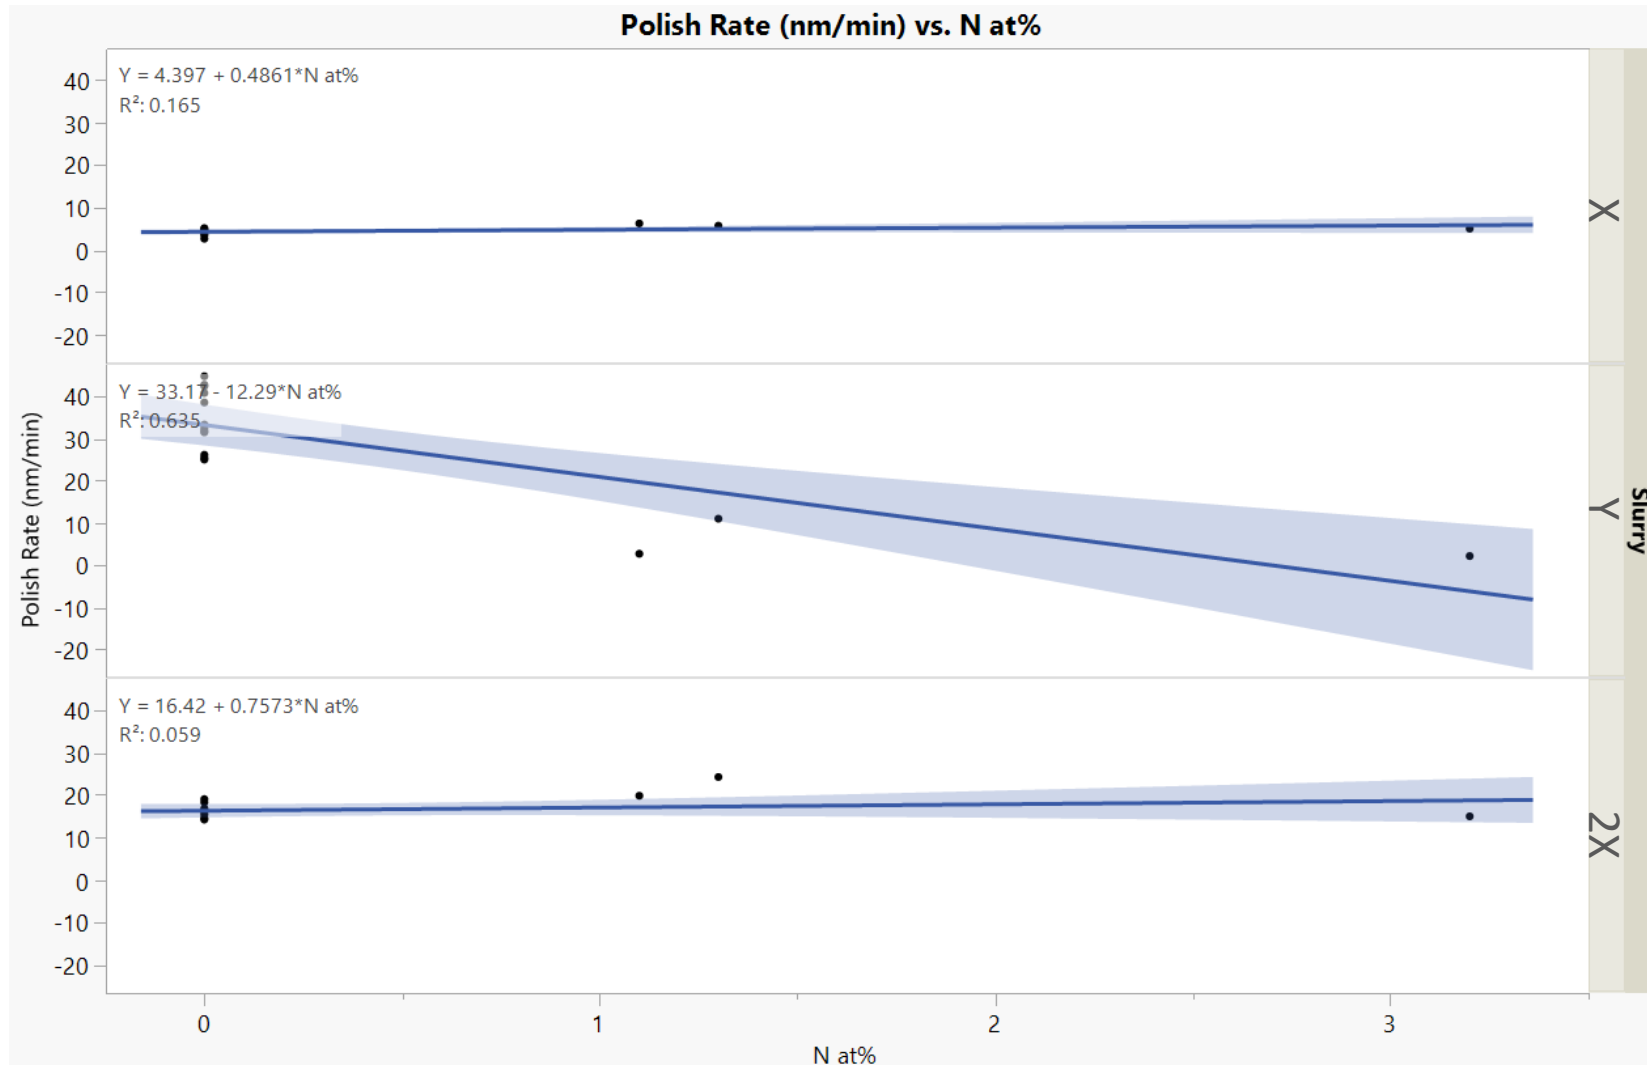

Attractive force between particle and surface, MRR increase

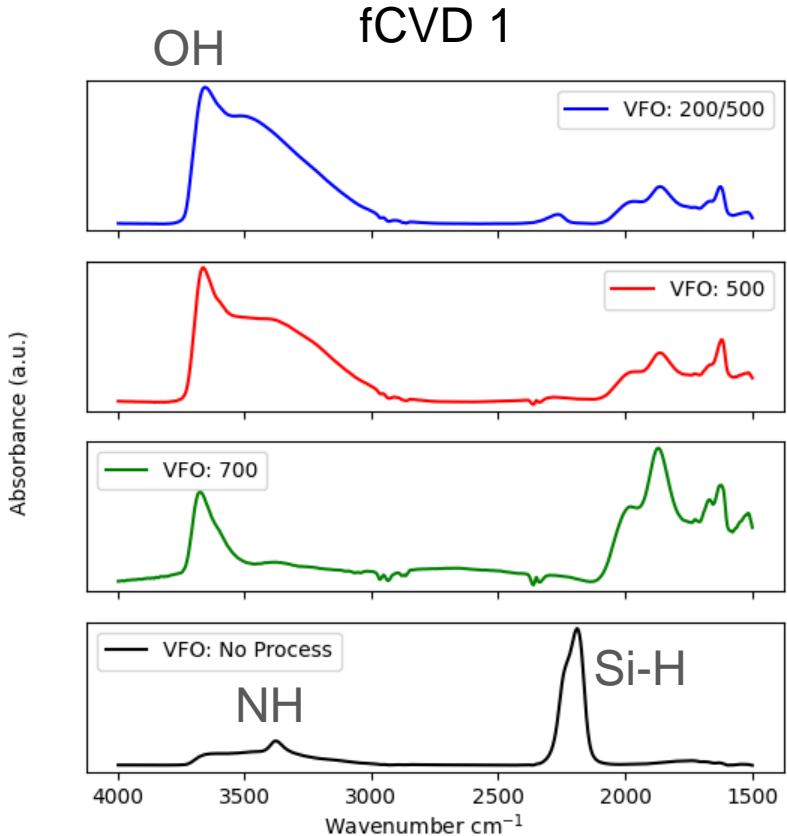

More generally abrasive action due to minimal electrostatic interactions on surface- repulsion and charge neutralization from NH<sub>3</sub><sup>+</sup>

# Nitrogen Content is Not Correlative to Polish Rates

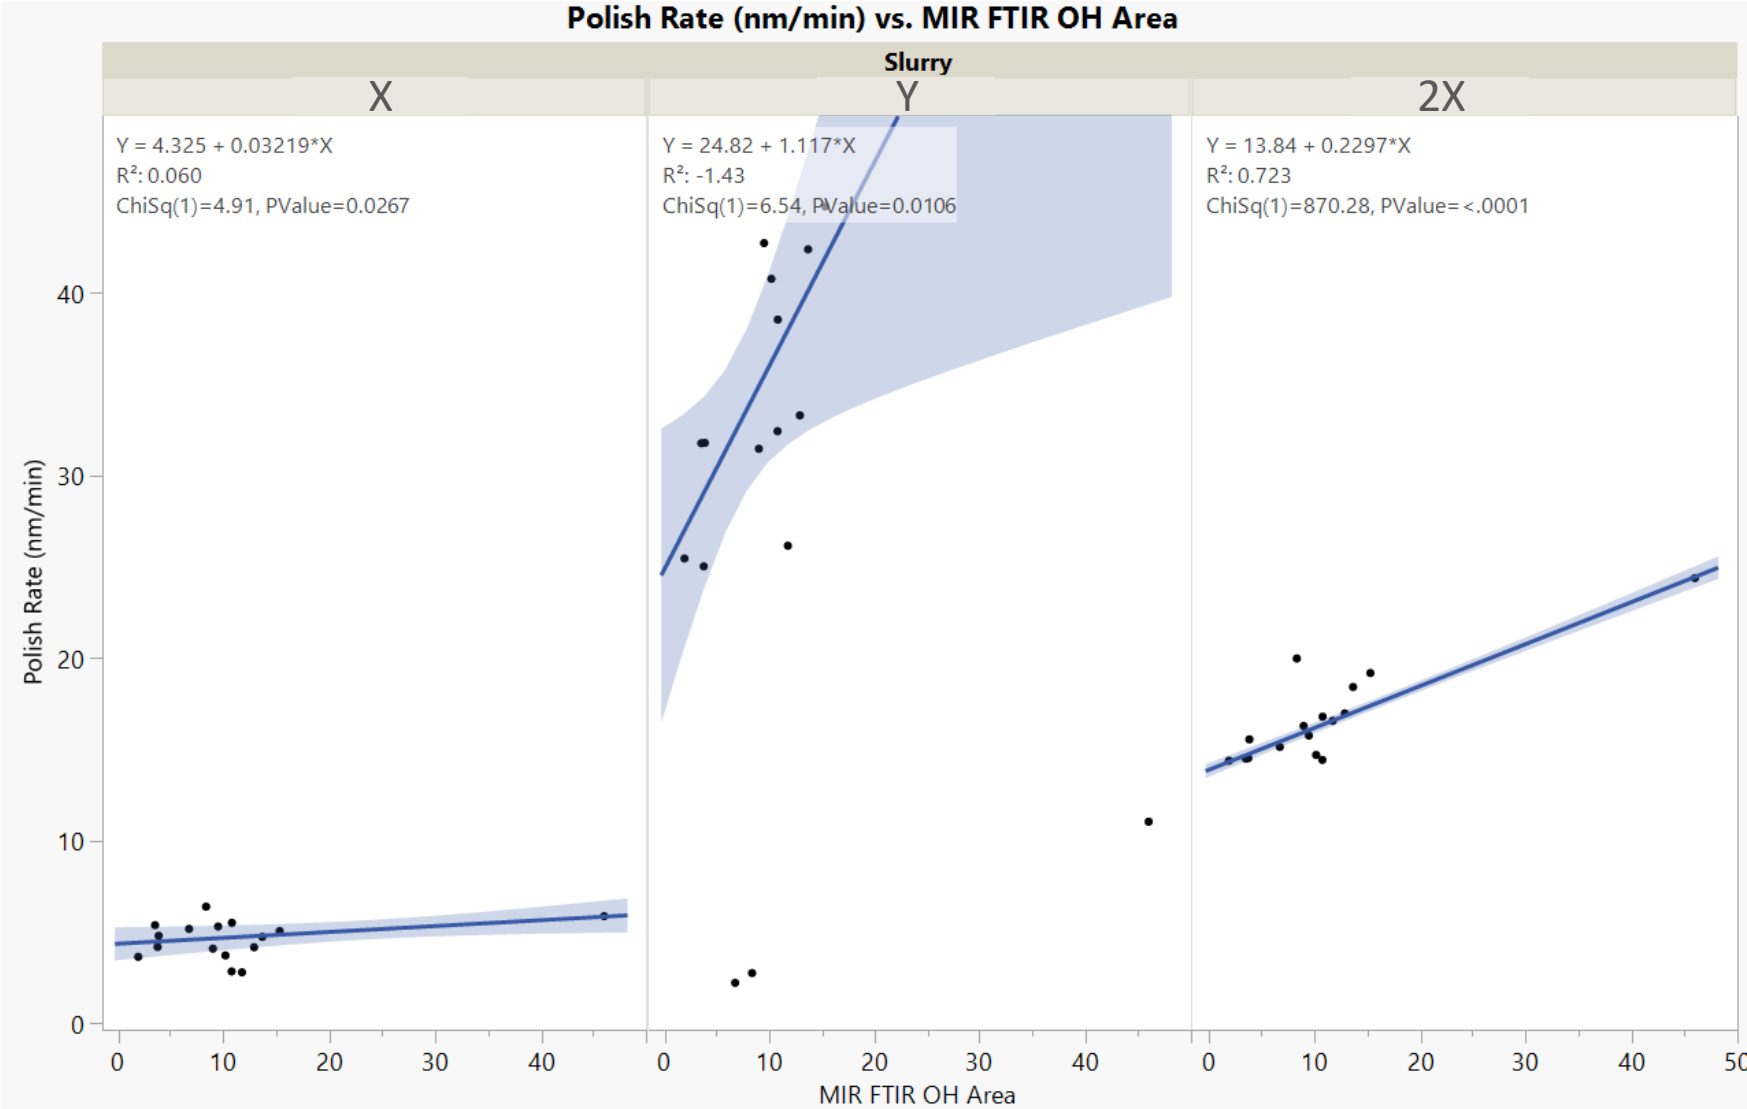

# FTIR Provides A More Direct Understanding of Anneal Effects

- In both fCVD films, the N and Si-H peak disappears after a steam anneal
- As the steam anneal gets more aggressive, the broad OH peak narrows and decreases

# FTIR –OH Area Is Not Independently Predictive of Polish Rates

# Why does a higher anneal condition lead to a lower polish rate?

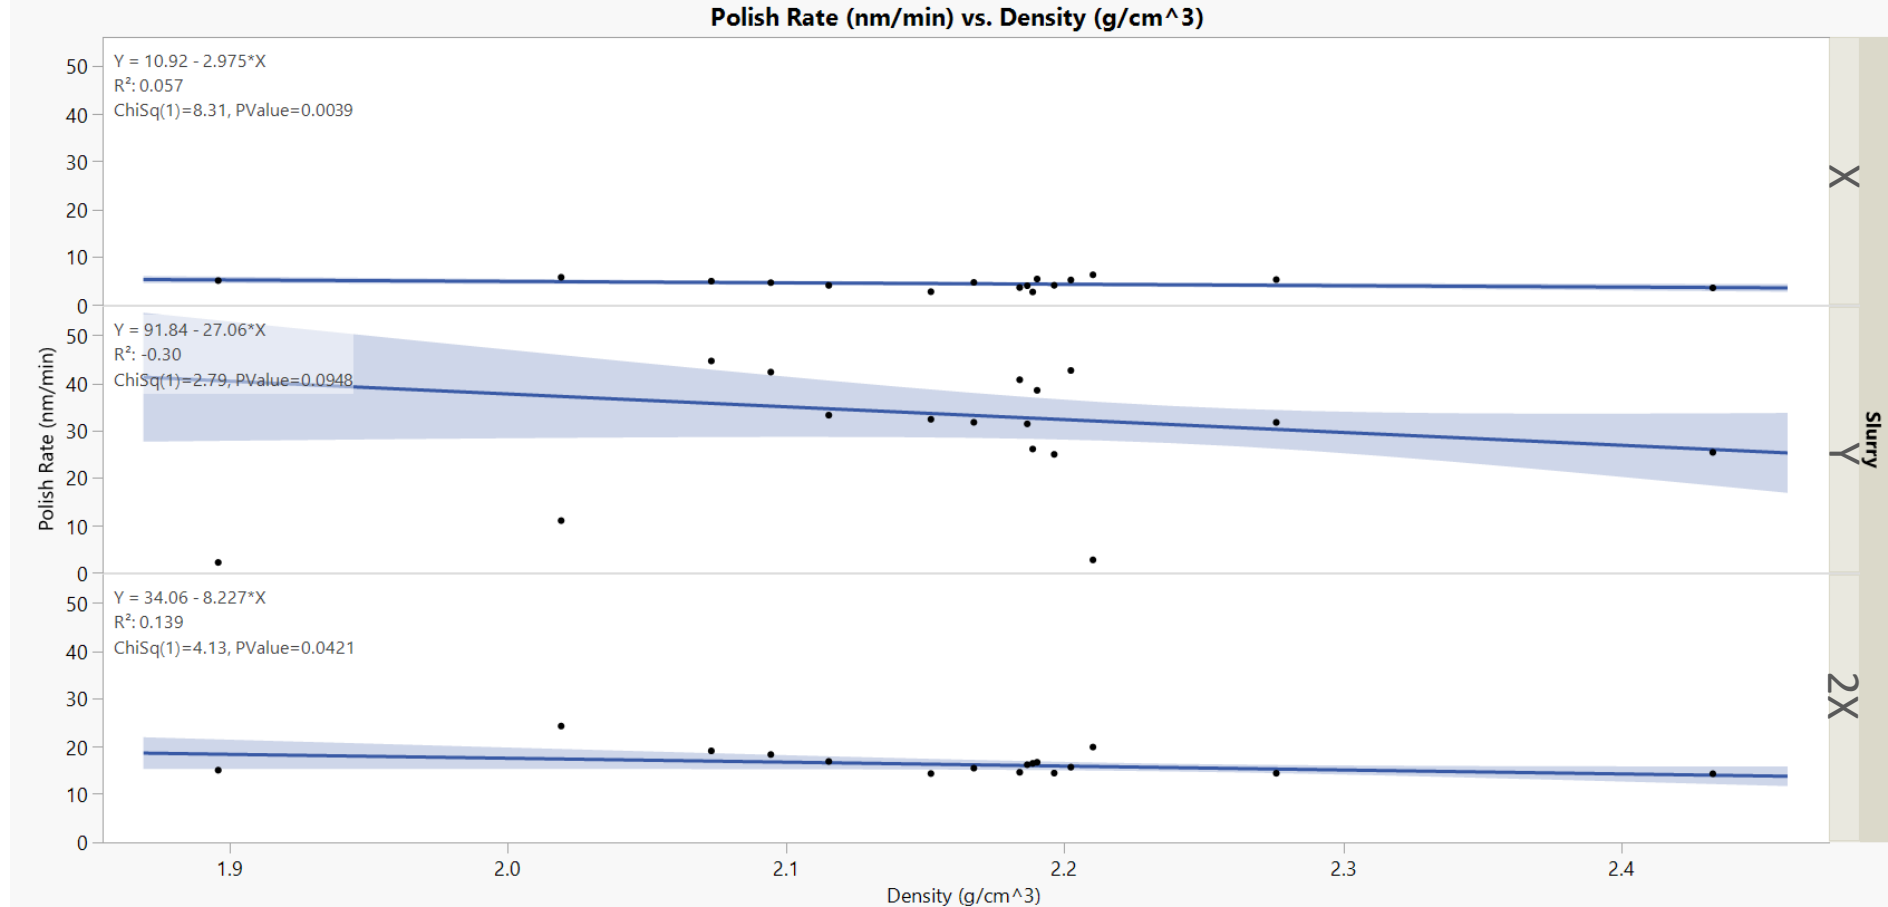

Contact angles show a clear trend- as the anneal gets more aggressive, hydrophobicity increases

# Density Data Further Reinforces WCA Findings

As the films are annealed, they also become denser- a result of hydrolysis into Si-O-Si

# Neither is Density Alone

Surprisingly, not that strongly correlated, but F-test suggests strong significance of the density in Slurry X ( $P < 0.05$ ) and Slurry 2X ( $P < 0.05$ )

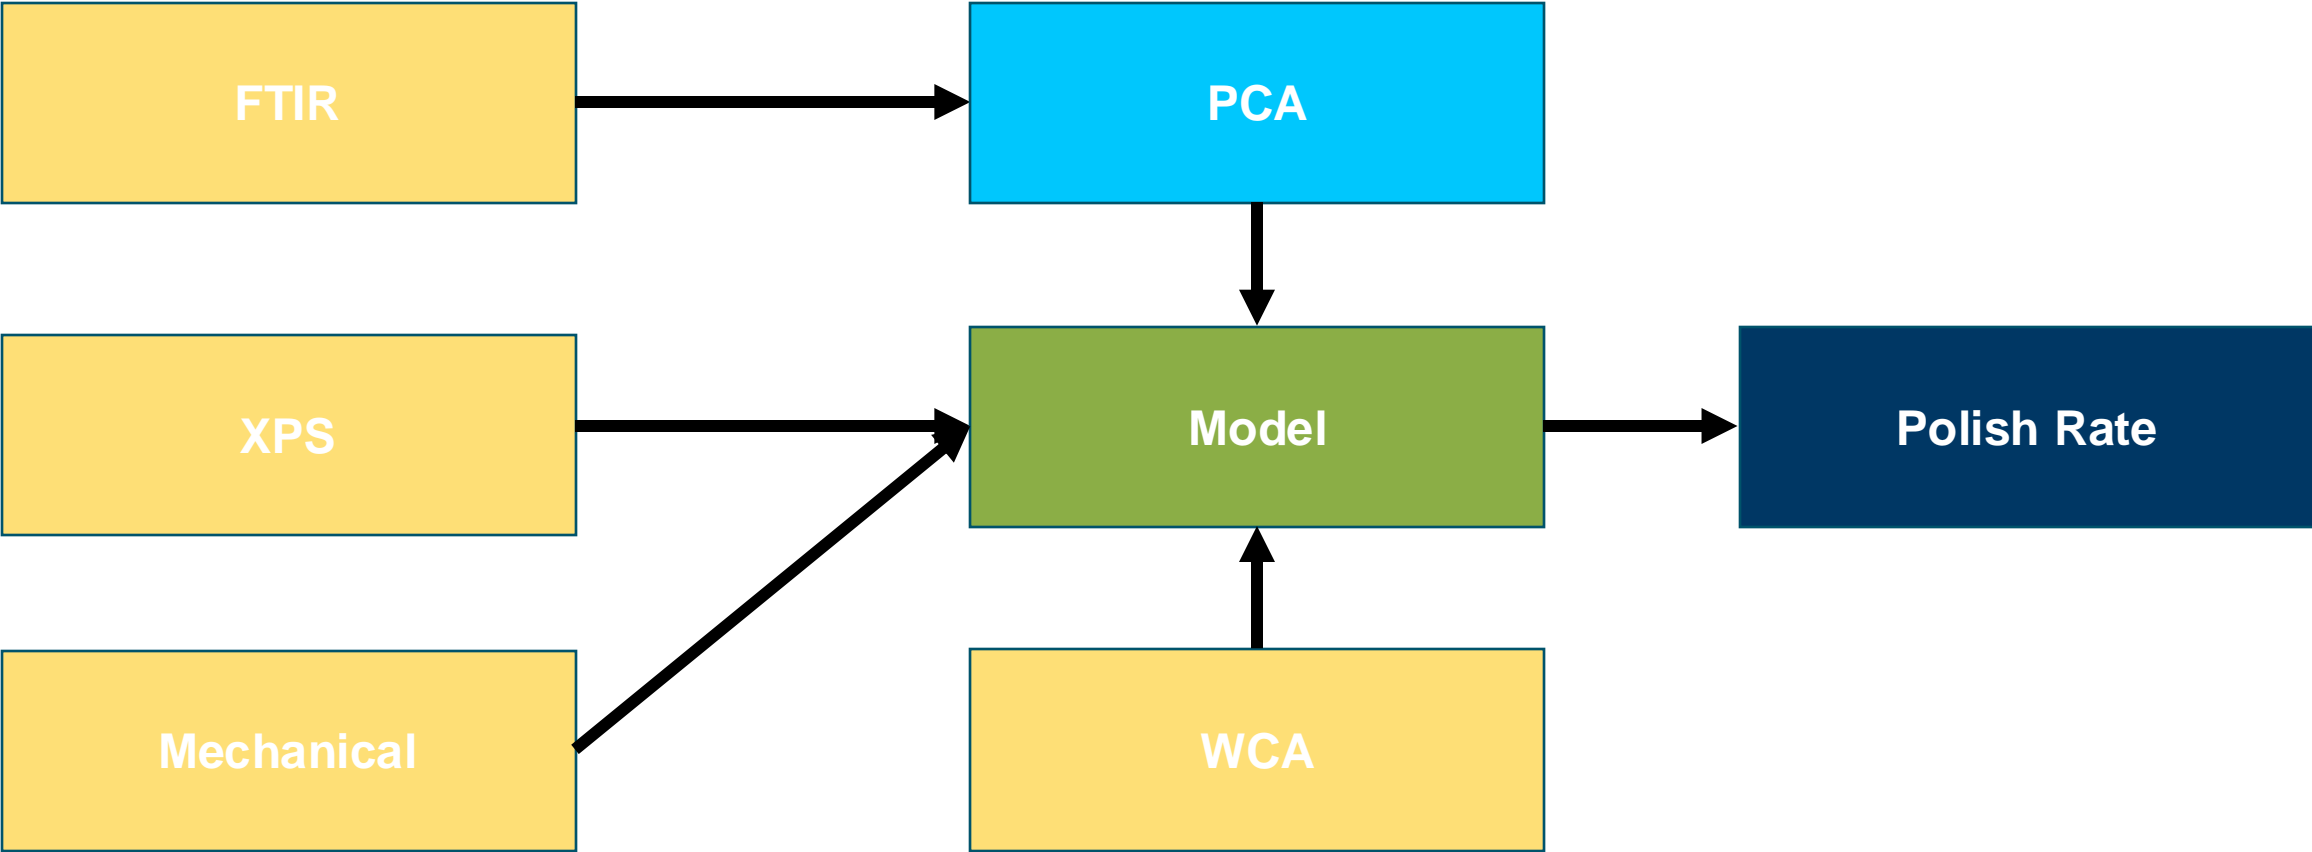

## Takeaways

- Particle Y enhances the polish rate for pure oxides
- Particle Y shows a negligible polish rate if films contain nitrogen (>1 at%)
- Nitrogen, oxygen and density are all related to polish rate ( $P < 0.05$ ) but are not 1:1 correlative

# ML Modeling

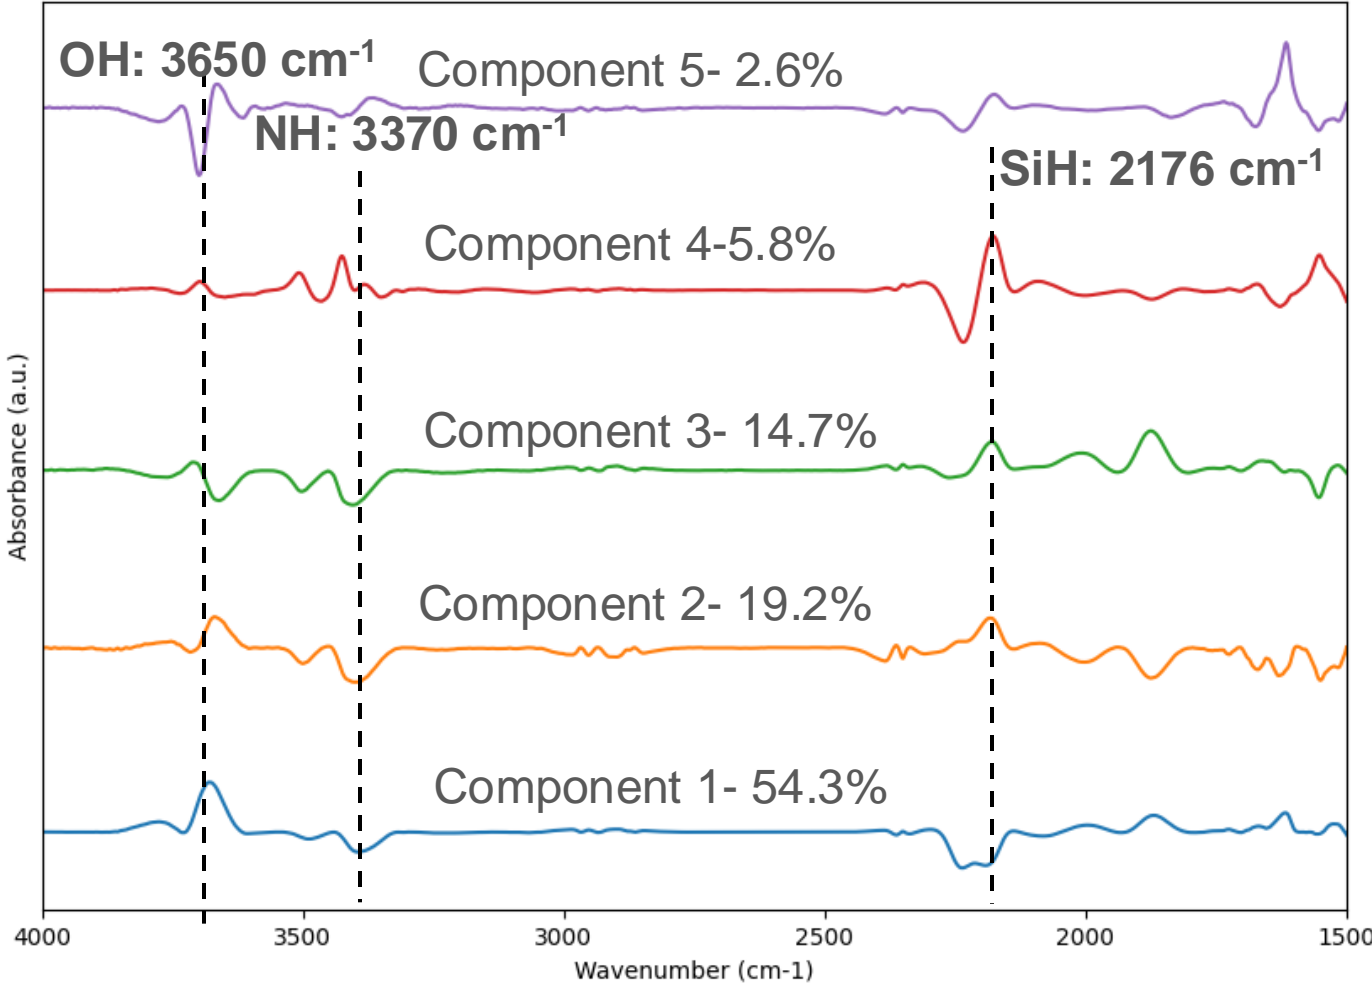

# If Surface Interactions Are Key, Can We Use Surface Spectra As Predictors of Polish Rate?

# PCA Crash Course

- In non math terms, a PCA (“Principal Component Analysis”) finds the features in a dataset that maximize variance.
- “What features in this data make one different than another?”
  - Component 1- maximizes variance, Component 2- 2<sup>nd</sup> most variance etc.
- Putting together the components in some unique weight will rebuild all the data (almost). Each weight is known as a score.
- This results in a lower-dimensional representation of data that still retains the most important patterns or structures.

# Modeling- FTIR MIR PCA

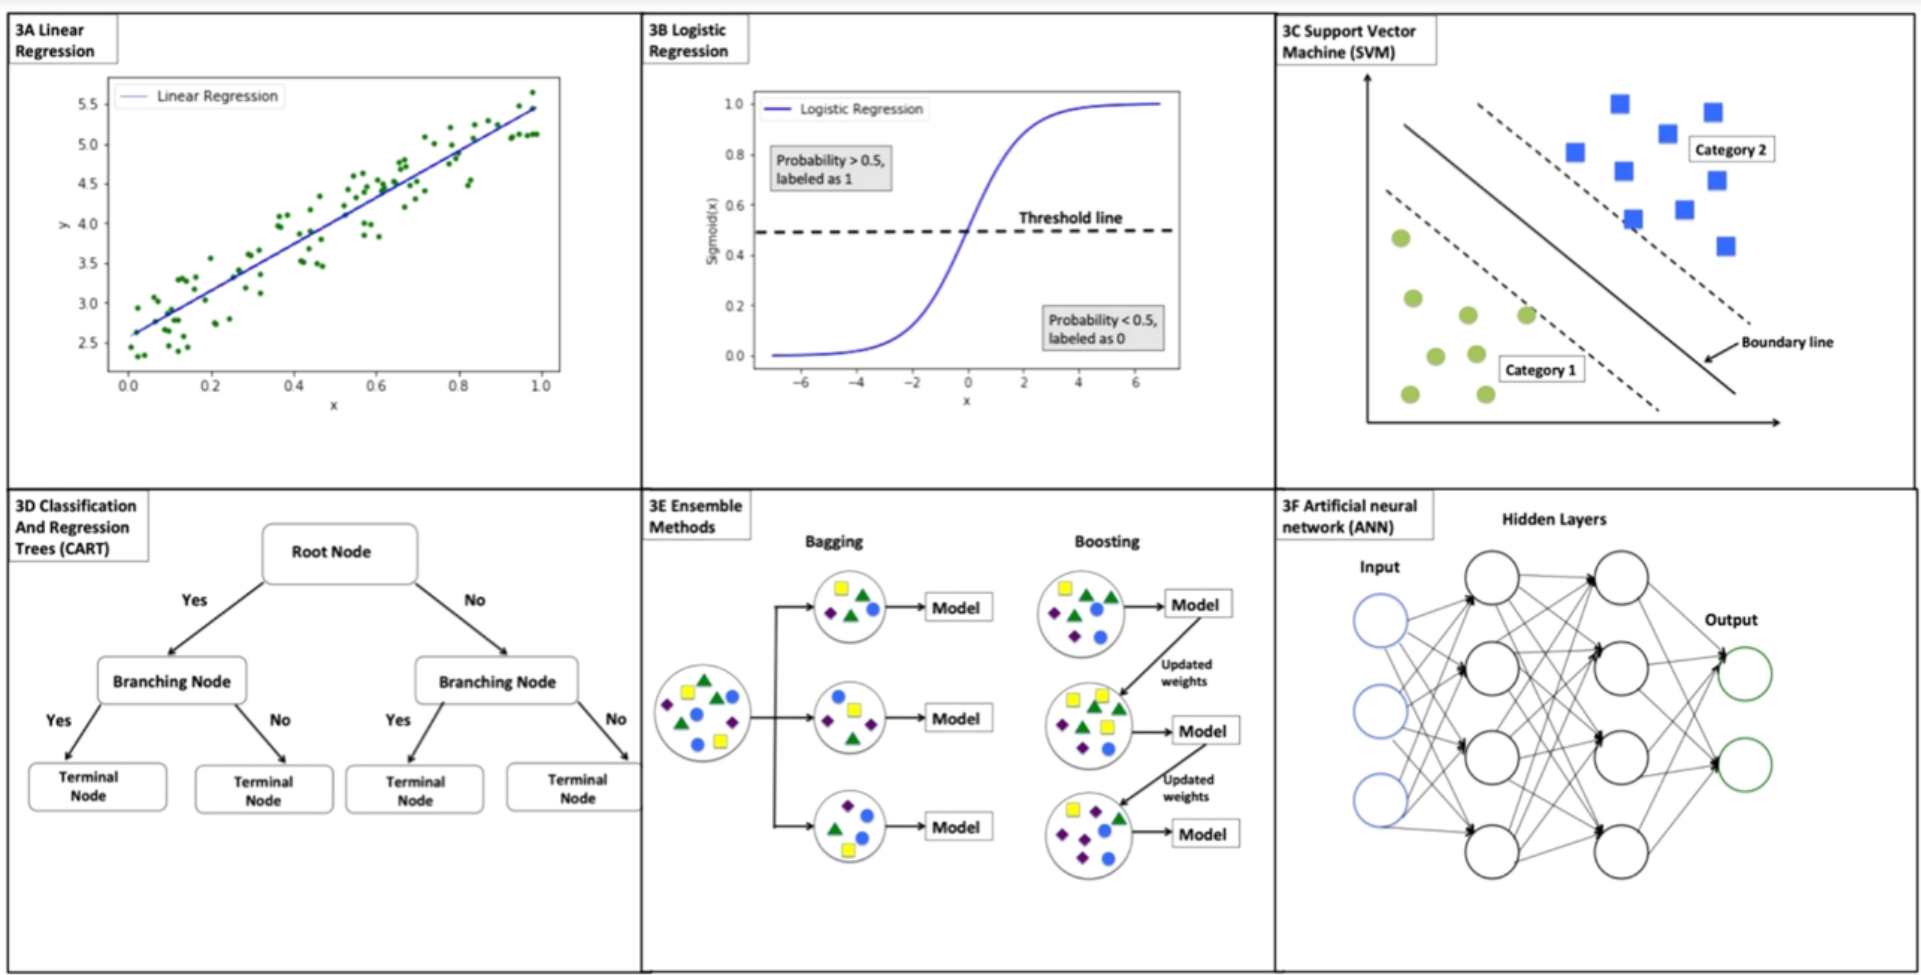

PCA analysis found impactful wavelengths, correctly identifying them as OH, NH and SiH peaks **without deconvolution**

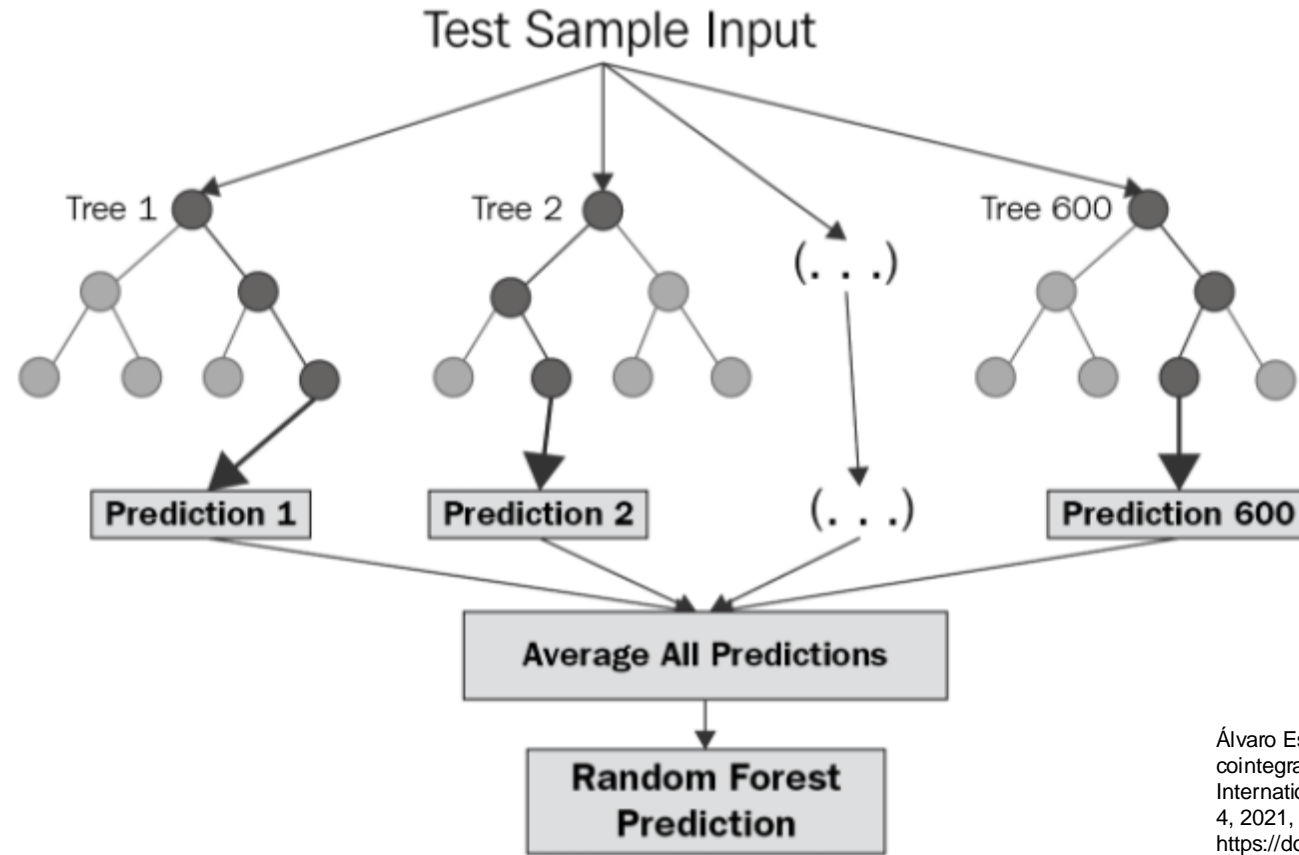

# Machine Learning Methods Crash Course

Lin, W., Chen, J.S., Chiang, M.F., & Hribar, M.R. (2020). Applications of Artificial Intelligence to Electronic Health Record Data in Ophthalmology. *Translational Vision Science & Technology*, 9.

General Guidance: Stay as simple as you can (start at linear regression and work higher)

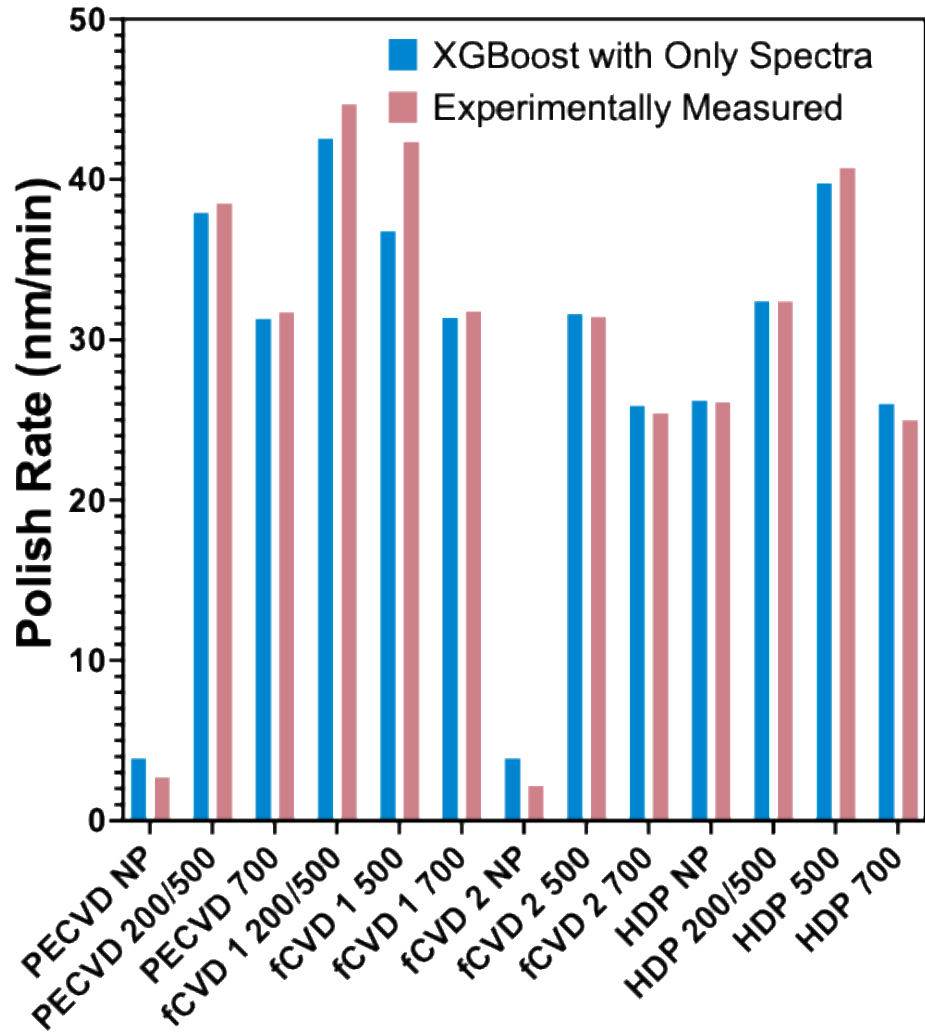

# Random Forest Crash Course

Álvaro Escribano, Dandan Wang, Mixed random forest, cointegration, and forecasting gasoline prices, International Journal of Forecasting, Volume 37, Issue 4, 2021, Pages 1442-1462, ISSN 0169-2070, <https://doi.org/10.1016/j.ijforecast.2020.12.008>.

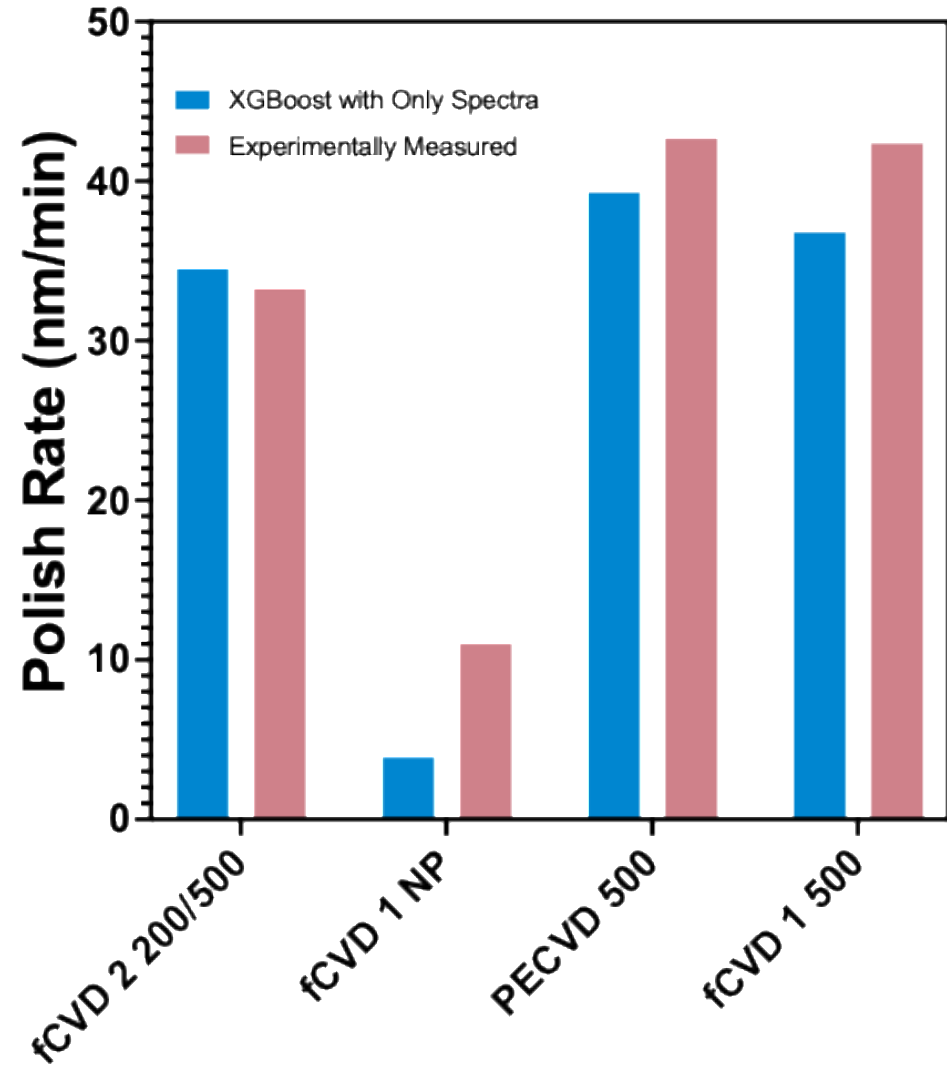

Each “tree” independently results in a solution based on different features. The average of these is our final solution.

# XGBoost Modeling w/Spectra Alone

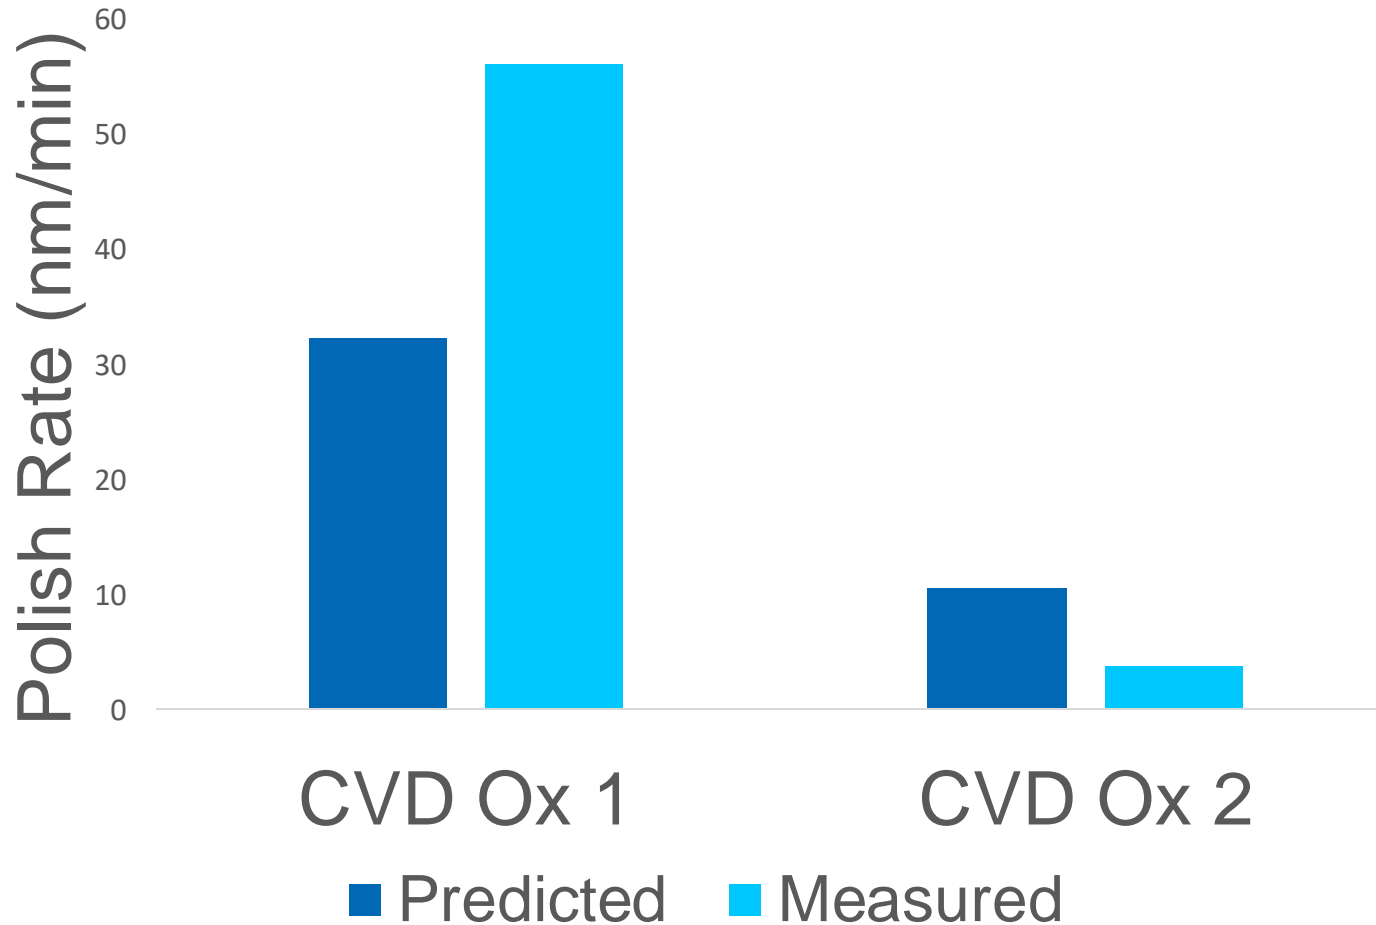

Train Dataset R2: 95.4%

Test Dataset R2: 87.4%

# What about films it has never seen?

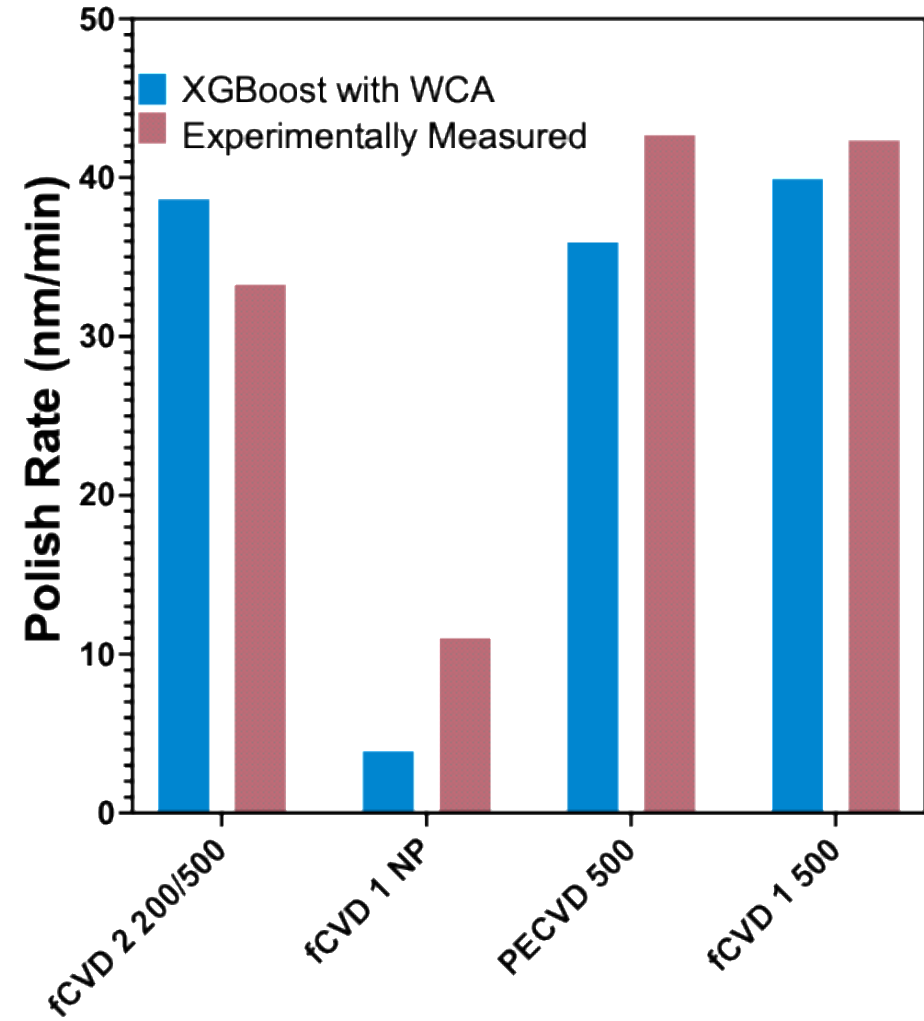

Definitely some overfit, but appears to be a solid classifier

# XGBoost Modeling w/WCA Added

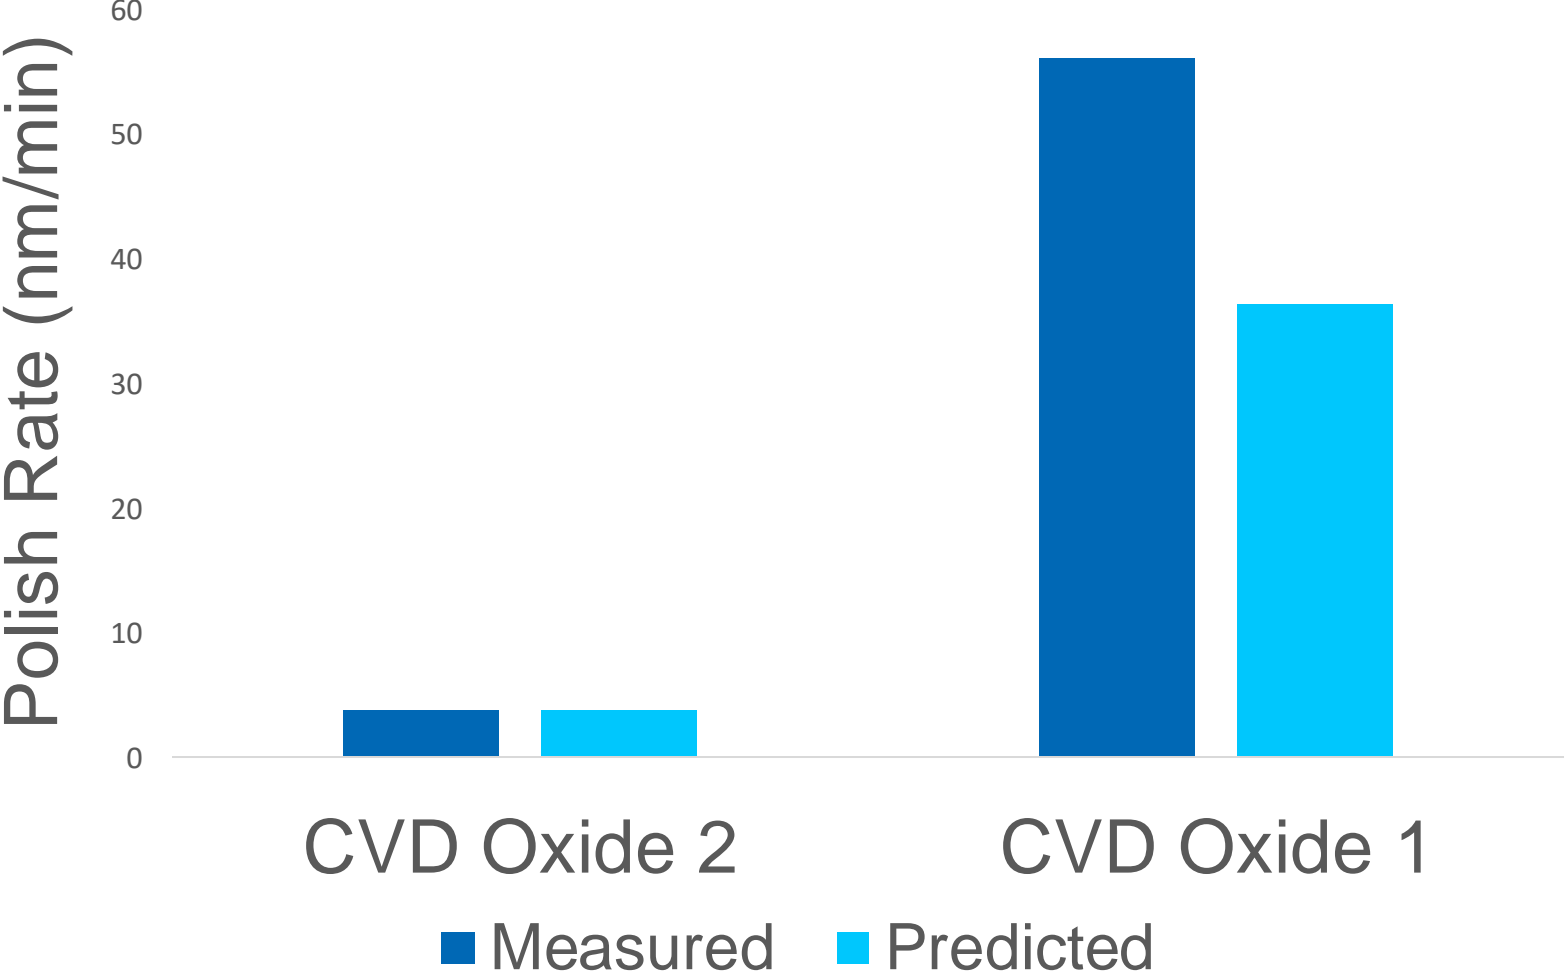

Train Dataset R2: 96.0%

Test Dataset R2: 85.7%

# XGBoost Modeling w/WCA Added

# The Modeling Approach Used Is A Balance

## Strengths

- Fully built on nondestructive techniques, allowing for faster iterating
- An extremely successful classifier- will it polish or will it not polish?
- Functions well as a regressor as well, with room for improvement
- The successful predictive use of only surface spectra supports the electrostatic interaction qualitative model

## Limitations

- Cannot capture extremes in polish rate ( $>40\text{nm}/\text{min}$ )- need to add more data points in the extremes
- Need to add more data on other moieties (carbon + nitrogen containing films) to build robustness

# Conclusions

- This is the **first successful modeling using noncontact metrology to predict oxide CMP polish rates** (to our knowledge)
- AI Models are powerful tools to deconvolve interacting variables in CMP with immediate use cases in R&D and pathfinding
- No single spectroscopic variable appears to be predictive of polish rate changes in a vacuum
- A 2-step model is proposed, where the first step is electrostatic interaction with the surface, and the second is chemical binding to the surface followed by removal
